4
The influence of surface projections, both totally and partially immersed in a turbulent boundary layer, on the distribution of heat-transfer coefficients has been determined on 20 configurations. Surface projections cause separations of the local flow; the extent of these separations both upstream and downstream and the magnitude of the resultant interference heat-transfer coefficients are dependent upon the size and cross-sectional shape of the projection, Mach number, Reynolds number, and boundary-layer thickness. The configurations of this investigation include both three-dimensional simple shapes and hardware-type configurations tested on a flat plate with a turbulent-boundary-layer-thickness variation of approximately 10 to 1. The extent of the interference region can be defined by static-pressure measurements, oil-flow technique, or by heat-transfer measurements.

The windward heating rates increase with decreasing boundary-layer thickness. A maximum value occurs when the projection height is equal to or greater than the boundary-layer thickness. The effects of Mach number and Reynolds number are confined to the immediate vicinity of the windward face of the projection. The magnitude of interference heating expressed as the ratio (at a particular thermocouple) of the heat-transfer coefficient with a protuberance to the heat-transfer coefficient without a protuberance increases with decreasing Reynolds number and increasing Mach number.

Interference heating in the vicinity of swept cylindrical projections depends upon direction of sweep (forward or back); for example, a cylinder swept back 45° has an interference heating rate 2.07 times that of the undisturbed flat plate, at 0° sweep an interference heating 6.83 times that of the flat plate, and swept forward 45° an interference

heating 11.14 times that of the undisturbed flat plate. On the cylindrical projection the lambda-footed bow shock causes a localized region of high heating. The location of this region is dependent upon the free-stream Mach number, boundary-layer thickness, and the ratio of cylinder diameter to boundary-layer thickness. Except for the sweptback cylinder the stagnation-line heating rates outside the interference region are predictable by existing theory. The flat-plate boundary layer on the sweptback cylinder increases the stagnation heat-transfer coefficients.

Location of a protuberance in the influence of another protuberance can cause large variation in the interference heating distribution. The most critical location is in the vicinity of the upstream projection shocks.

In the wake of a projection placed immediately behind another projection the heating rates are negligible. Further downstream, the wake heat-transfer distribution is greater than that in the undisturbed flow. Cylinders mounted in the wake of other projections and aligned with the flow so that the space between cylinder wall and flat-plate surface is less than 0.01 of the boundary-layer thickness still have heating rates higher than those of the undisturbed region.

INTRODUCTION

The design of an efficient launch vehicle of long-range capabilities requires minimum structural weight and maximum fuel volume. The present concept of missile design is to utilize extremely thin skin with internal pressure to prevent shape deformation. To provide maximum fuel volume, the piping, instrumentation, antenna, and so forth, are located on the exterior portion of the missile; this thus produces protuberances partially or completely immersed in the missile boundary layer. The effect on heat transfer of surface roughness and protuberances completely immersed in the boundary layer has been the subject of several investigations (refs. 1 to 5). It is the purpose of this investigation to obtain experimentally more detailed information on the distribution of heat transfer on the protuberance and adjacent skin area for large protuberances that are totally or only partially immersed in a turbulent boundary layer. Two classes of protuberances were investigated: one group consists of simple geometric shapes to simplify the shock-boundary-layer interaction and the analysis of the resultant flow field and the second group consists of scaled models of specific components of a typical launch vehicle.

Each protuberance was tested at Mach numbers of 2.65, 3.51, and 4.44 through a range of Reynolds number per foot from 1.3×10^6 to 4.7×10^6 .

The models were tested on a flat plate with a turbulent-boundary-layer-thickness variation of 10 to 1. Pressure distributions in the vicinity of the projections were also obtained. The oil-flow-visualization technique (ref. 6) was used to determine the nature of the flow in the vicinity of the projections.

SYMBOLS

b	local skin thickness, ft
c	specific heat of skin material, Btu/lb-°R
c_f	local turbulent skin-friction coefficient
c_p	specific heat of air at constant pressure, Btu/lb-°R
C_p	pressure coefficient
ΔC_p	variation in pressure coefficient
d	diameter of cylinder, in.
g	acceleration due to gravity, ft/sec ²
h	measured heat-transfer coefficient, Btu/ft ² -sec-°R
h_c	measured heat-transfer coefficient including conduction term, Btu/ft ² -sec-°R
h_L	theoretical heat-transfer coefficient for laminar flow on cylinder of infinite length, Btu/ft ² -sec-°R
h_o	measured heat-transfer coefficient on flat plate alone, Btu/ft ² -sec-°R
$h_{o,c}$	measured heat-transfer coefficient on flat plate alone, including conduction term, Btu/ft ² -sec-°R
K	protuberance height, in.
k	coefficient of thermal conductivity, Btu/ft-sec-°R
l	length, ft

M	free-stream Mach number
ΔM	variation in free-stream Mach number
N_{St}	Stanton number, $\frac{h}{(\rho V c_p g)_{\infty}}$
$N_{St,c}$	Stanton number including conduction, $\frac{h_c}{(\rho V c_p g)_{\infty}}$
p_s	static pressure, lb/sq ft
$p_{t,2}$	total pressure just downstream from a normal shock wave, lb/sq ft
R	Reynolds number per foot, $\frac{\rho V l}{\mu}$ ($l = 1$ ft)
R_x	Reynolds number based on distance x
T_e	effective stream air temperature at wall, some temperature which gives a thermal potential that is independent of heat- transfer coefficient (sometimes noted as recovery temperature), $^{\circ}R$
T_w	wall temperature, $^{\circ}R$
T_t	stagnation temperature, $^{\circ}R$
t	time, sec
Δt	variation in time, sec
V	velocity, ft/sec
w	specific weight of skin material, lb/sq ft
x	distance along longitudinal axis, in.
y	distance from longitudinal axis, in.
z	vertical distance from flat plate, in.
δ	boundary-layer thickness, in.

APPARATUS, MODELS, AND HEAT-TRANSFER AND PRESSURE INSTRUMENTATION

Wind Tunnel

This investigation was conducted in the high Mach number test section of the Langley Unitary Plan wind tunnel. This variable-pressure, continuous-flow tunnel has an asymmetrical sliding-block nozzle that permits continuous variation in the test-section Mach number from 2.3 to 4.65; this facility is described in reference 7.

Flat Plate and Support Structure

To determine the effect of projections on the distribution of heat transfer on the adjacent skin, the projections are mounted on a 4-foot by 5-foot flat plate instrumented with both thermocouples and static-pressure orifices. The location of the 84 thermocouples and the 10 pressure orifices on the test surface and the relative position of several projections are given in table I and illustrated in figure 1. (An index to the tabular data is included immediately before the tables.)

The laminated flat plate, as illustrated in figure 2, consists of a 0.050-inch-thick stainless-steel test surface insulated from the support surface by a 3/8-inch-thick hexagonal fiber-glass honeycomb. The honeycomb was bonded to the test surface and to a 1/8-inch-thick filler plate. To prevent shearing of the bond due to thermal gradients, the filler plate was cut, after bonding, into 8-inch by 8-inch sections and each section was secured to a steel backing plate by a button that allowed each segment to slide relative to the backing plate.

The test plate, as an integral unit, was mounted at three positions in the tunnel to obtain a range of boundary-layer thicknesses. The maximum boundary-layer thickness was obtained by mounting the flat plate on the test-section access door and flush with the tunnel side wall to utilize the normal tunnel side-wall boundary layer. Two other boundary-layer thicknesses were obtained by positioning the test plate at two positions on a 4-foot by 10-foot wing-shaped support assembly. The wing-type support was attached to the tunnel side walls and spanned the test section on the horizontal center plane. The leading-edge wedge of the support assembly, as illustrated in the view of the upper surface in figure 3, was aligned so that no flow deviation occurred on the test surface and the pneumatic seals, illustrated in the assembly photograph of the wing support in figure 4, prevented the flow from the structural support side from influencing the test surface. The test surface mounted flush with the bottom of the support assembly is illustrated in figure 5. The lower surface of the wing support contained two interchangeable panels (test plate and filler plate) that positioned the instrumented flat plate either 1 foot or 5 feet downstream from the leading edge, as illustrated in figure 6. The filler plate is similar in construction to the test plate and had eight thermocouples located at the positions shown in figure 7.

2
4

Four inches from the leading edge of the support structure a 1-inch band of No. 60 carborundum grit was used as a boundary-layer trip (fig. 6) for all tests conducted on the flat plate mounted along the horizontal center plane of the tunnel.

Projections

Two types of projections were included in this investigation: Three-dimensional simple geometric shapes and more detailed hardware-type models. Each model had a uniform skin thickness of 0.050-inch stainless steel with a backing of 0.25-inch-thick micarta that was relieved in the vicinity of each thermocouple. The backing material acted as a skin stiffener and prevented distortion or buckling of the models. All models were secured to the flat plate and were insulated from the test surface by a 1/16-inch-thick sheet of micarta.

Thin-walled pressurized missiles require circumferential stiffener rings. From an analysis of the data obtained in a narrow band (in this analysis 5 inches wide) along the flat-plate center line, the three-dimensional models in figure 8 show a two-dimensional section to the flow. The four stiffener models were tested in the maximum thickness boundary layer. The basic model (fig. 8(a)) represents the external stiffener with the minimum weight. The 2-inch by 4-inch rectangular stiffener is mounted on the flat plate with the 4-inch dimension normal to the flat plate and the 2-inch by 4-inch surface parallel to the

direction of flow. To decrease the abrupt flow on the windward face, the 2-inch by 4-inch model was faired by a $1/4$ round cylinder (fig. 8(b)). Minimum flow deviation for this investigation was obtained by fairing the upstream face with a 30° wedge as shown in figure 8(c). To eliminate discontinuities of surface joints between the upstream fairing and the basic 2-inch by 4-inch rectangular stiffener, a separate model was made for each configuration. Each model was instrumented with 24 thermocouples. The location of the 12 thermocouples on the 1-inch by 2-inch rectangular stiffener is shown in figure 8(d) and is listed in table I.

The junction of the externally mounted piping with the skin was simulated by the 2.8-inch-diameter right circular cylinder illustrated in figure 9. The cylinder was mounted normal to the flat plate and was instrumented with 24 thermocouples; 8 thermocouples were located along the stagnation line and the remaining thermocouples were located at meridian angles of 45° , 90° , and 180° at four axial stations along the cylinder. A dummy cylinder was located at four positions upstream from the instrumented cylinder to determine the effect of wake on the heat-transfer coefficients. The dummy and instrumented cylinders were tested in tandem at spacings of 3.2 and 6.4 diameters. The instrumented cylinder was also tested with dummy cylinders at two offset locations 3.2 diameters upstream; a line connecting the centers of the cylinders forms angles of $26\frac{1}{2}^\circ$ and 45° with the tunnel center line. The location of the instrumented and dummy cylinders is shown in figure 1.

The instrumented cylinder was also tested with a 9-inch by 14.10-inch cap plate having a 10° wedge (fig. 10) to eliminate tip effects and more closely simulate an infinite cylinder.

The effect of aspect ratio on both single and multiple right-circular-cylinder configurations was determined by tests with 1.4-inch-diameter cylinders. The 1.4-inch-diameter instrumented cylinder illustrated in figure 11 had 12 thermocouples.

The variation of heat transfer with sweep was evaluated on the 2.8-inch-diameter cylinder instrumented with 24 thermocouples illustrated in figure 12. The sweep angle was 45° forward and 45° back.

The aforementioned projections are applicable to a fundamental approach and understanding of the parameters that are important in the flow field of a flat-plate boundary layer. However, detailed information of the distribution of heat transfer on complex configurations (that is, the lox line and helium pressurization lines on a typical launch vehicle) is of considerable importance to the entire field of aerodynamic heating. Consequently, the following hardware shapes were also tested.

The stiffener model with a trapezoidal cross section (fig. 13) simulates the circumferential conduit fairing typical of that used with some launch vehicles. The windward face of the 8.68-inch by 1.00-inch rectangular stiffener was faired with a 30° wedge to simulate a cableway; the model was instrumented with 12 thermocouples.

The influence of external piping, with its axis aligned to the flow, on the flat-plate local heat-transfer coefficients was determined on the configurations illustrated in figures 14(a), 14(b), and 14(c). On the configurations in figures 14(a) and (b), fairings have been used to diminish the abrupt flow discontinuity resulting from external piping mounted normal to the surface. The model in figure 14(a) duplicates a helium line; it has a hemicylindrical leading edge swept 45° and also a spherical segment for clearance of an internal valve. The external pipe of the model has a cylindrical shroud 2.02 diameters long for a simulated cover of a pipe expansion joint. The axis of the external pipe was 1.13 inches from the plate. The configuration in figure 14(b) has a 26° cone cylinder to further attenuate the flow discontinuity at the pipe-plate juncture. The axis of the streamwise pipe model is 1.32 inches from the plate surface. Both of these configurations had 24 thermocouples installed on the fairing and piping and are relatively aerodynamically clean. The prerequisite of minimum weight precludes the use of large fairings, and on some of the piping normal to the surface, the elbows, valves, circumferential rings, and expansion bellows are exposed to the airflow. The uninstrumented model in figure 14(c) is a representative lox line with a nominal diameter of 2.75 inches. The cylindrical axis of this model was located 1.605 inches above the flat-plate surface.

Photographs of typical protuberances are presented as figures 15 to 31.

Thermocouple Instrumentation

All thermocouples were 24-gage iron-constantan wire; each thermocouple was soldered with pure tin in a 0.030-inch-diameter hole through the model surface.

The thermocouple outputs were recorded on a multichannel sequential analog to digital conversion system described in reference 8. The thermocouple voltages were sampled every $1/2$ second, converted into digital form, recorded on magnetic tape, and converted to punchcards for machine calculation.

The stagnation temperatures for tests utilizing the wing-type support structure were determined by temperature probes mounted on the sting support system downstream from the models as illustrated in figure 3. The sidewall-mounting probes were 12 inches from the tunnel side wall for the tests in the tunnel side-wall boundary layer.

Pressure Instrumentation

The primary purpose of the present investigation was to determine heating rates; consequently, only a slight amount of pressure instrumentation was incorporated in the tests. The static-pressure orifices in the test surface were used to determine the extent of the effect of the projection on the flat-plate surface pressures. The static pressures were measured with individual electrical transducers. Total-pressure profiles were obtained to determine the nature and magnitude of the boundary layer at the three test plate positions. The 30-tube rake illustrated in figure 32 was used to determine the boundary-layer thickness at 40.47 and 116.47 inches from the leading edge on the 10-foot flat plate. The tunnel side-wall boundary layer was measured at the position of the instrumented right circular cylinder with the large pressure rake shown in figures 33 and 34. Boundary-layer-rake static- and total-pressure tubes were connected to valves that sequentially sampled 48 pressures on a single electrical transducer. The transducer output was digitized and recorded on punchcards for machine calculation. The free-stream and stagnation pressures were measured by precision mercury manometers.

ACCURACY

The precision mercury manometers have an accuracy of $1/2$ lb/sq ft and therefore the accuracy of the pressure system is limited to the electrical transducer. The deviation in test-section Mach number without the horizontal support structure is listed as follows:

M	R	$\pm \Delta C_p$	$\pm \Delta M$
2.65	3.98	0.011	0.02
	2.58	.016	.02
	1.33	.032	.02
3.51	4.05	.013	.05
	2.86	.019	.05
	1.65	.033	.05
4.44	4.69	.017	.06
	3.24	.024	.06
	2.16	.037	.06

One of the characteristics of the Langley Unitary Plan wind tunnel (refs. 7 and 9) is that the expansions of the nozzle originate on the lower surface and are canceled on the upper surface. The 10-foot flat surface extends upstream from the test section and apparently intercepts a portion of the nozzle expansion. The resultant compression and reflected expansions cause a deviation in Mach number level that is dependent upon R . The local values of M for two positions on the flat plate are presented in the section entitled "Boundary layer."

Elementary tests conducted on the flat plate and utilizing radiant heat source indicate that losses due to conduction through the fiber-glass laminated honeycomb insulation, convection in the honeycomb cells, and the added mass of the glue line and tape bonding the honeycomb to the stainless-steel skin could be as large as 23 percent.

L
2
0
2
4

The accuracy of the temperature measurements based upon thermocouples wire calibration, cold junction, and recorder resolution is $\pm 2^\circ \text{F}$ as determined in reference 8.

The accuracy of the heat-transfer coefficients also previously determined in this facility (ref. 10) indicates values as shown in the following table:

Heat-transfer coefficient	Accuracy
>0.0150	± 10 percent
0.0010 to 0.0150	± 15 percent
<0.0010	± 20 percent

DATA REDUCTION

Pressure Data

The static pressures on the flat plate are presented as free-stream pressure coefficients. The Mach number distribution in the boundary layer is determined from the total-pressure survey rake by assuming that the static pressure is constant through the boundary layer and of the magnitude determined from the outboard static-pressure tube on the rake of figure 32 and the magnitude of the inboard static-pressure tube on the rake illustrated in figure 33.

Heat-Transfer Data

The heat-transfer coefficients were obtained from transient skin temperatures resulting from a stepwise increase in stagnation temperature as shown in reference 8. The following relation, which assumes constant temperature through the skin, negligible lateral heat flow, negligible heat flow to the model interior, and no heat losses due to radiation, was used:

$$h = \frac{wc \, dT_w/dt}{T_e - T_w}$$

This equation was rewritten in the following form for complete machine calculation:

$$h = \frac{wc(T_{w,m} - T_{w,0})}{\frac{T_e}{T_t} \sum_{0}^{m-1} (T_t)_i \Delta t - \sum_{0}^{m-1} (T_w)_i \Delta t}$$

The summations are evaluated over increments of time according to the trapezoidal rule, and the ratio T_e/T_t is experimentally determined. The effect of conduction through the model skin was determined from the following relation:

$$h_c = \frac{wc(T_{w,m} - T_{w,0}) - kb \sum_{0}^{m-1} \left(\frac{\partial^2 T_w}{\partial x^2} + \frac{\partial^2 T_w}{\partial y^2} \right)}{\frac{T_e}{T_t} \sum_{0}^{m-1} (T_t)_i \Delta t - \sum_{0}^{m-1} (T_w)_i \Delta t}$$

A detailed discussion of this method of data reduction is also presented in reference 8.

The Stanton number was determined from free-stream conditions; it is given as

$$N_{St} = \frac{h}{(\rho V c_p g)_{\infty}}$$

DISCUSSION OF RESULTS

Flow Visualization

The oil-flow technique described in reference 6 was used to define the flow near the flat-plate surface for 10 different protuberances mounted in the maximum boundary-layer thickness. The flow field is made visible by coating the model surfaces with a high-viscosity oil having in suspension a fluorescent green dye that becomes luminescent when exposed to ultraviolet light.

To obtain oil-flow photographs the instrumented flat plate was mounted in the tunnel side wall with a resultant boundary-layer thickness of 6 inches. The flow field over the entire flat plate was recorded with two wide-angle-lens cameras mounted in the opposite wall. However, the distortion of the wide angle lenses prevented superposition of the two pictures. The oil-flow photographs were made at a free-stream Mach number of 3.51 and a nominal Reynolds number per foot of 3×10^6 . The slight asymmetry of the upstream boundary of the interference region indicates that there is some cross flow in the tunnel side-wall boundary layer. The slight effect of free-stream Mach number was determined on the single cylinder that was tested at Mach numbers of 2.65, 3.51, and 4.44. The flow field for the three external stiffener models illustrated in figure 8 are shown in figures 35(a), (b), and (c). The effect of the protuberance on the flow field is discussed in terms of projection height K . The flow field on the leeward side of the models is similar for all three models. Along the leeward face a dead-air region extends downstream about $1/4K$. A loop vortex originating at the stiffener ends extends along the leeward side of the models with the vortex filament approximately $1K$ downstream from the model.

The flow field for a 2-inch by 4-inch rectangular stiffener is shown in figure 35(a). The bow shock wave separates the boundary layer upstream from the model and reverse flow extends a distance of $4K$ upstream from the front face. In figure 35(b) the flow pattern for the 2-inch by 4-inch rectangular stiffener faired with a $1/4$ round fairing of the windward face shows that flow separation extends $2.8K$ upstream from the front face. The flow field on the windward face was washed clean at a Reynolds number of 3.5×10^6 . As shown in figure 35(b), at a reduced Reynolds number of 2.0×10^6 the limit of reverse flow on the windward face is very clear. The effect of fairing the windward face of the rectangular stiffener with a 30° wedge is shown in figure 35(c). The extent of reverse flow is reduced to $1.4K$ upstream from the leading edge of the wedge. The demarcation line of flow separation, visible on the wedge face, is approximately $0.3K$ from the flat-plate surface. Downstream, the loop vortex flow for the wedge is more clearly defined than that for the rectangular stiffener.

The oil-flow patterns for a single right circular cylinder mounted normal to the flat plate at free-stream Mach numbers of 2.65, 3.51, and 4.44 are shown in figure 36. The interaction of the cylinder bow shock wave with the boundary layer on the flat plate results in the high-pressure air behind the shock feeding upstream in the subsonic portion of the boundary layer; this causes a local thickening in boundary layer and, consequently, a lambda footed bow shock wave. This lambda footed bow shock wave causes two defined lines in the oil-flow pattern. The outermost line is the limit of reverse flow and the innermost line encloses the region of maximum turbulence in which the oil is almost completely removed. Increasing the Mach number from 2.65 to 4.44 increases the upstream extent of reverse flow from 1 cylinder diameter to 1.2 diameters and also increases the width of the flat-plate area affected by the cylinder. The flow on the leeward side of the cylinder is similar for all three Mach numbers where a dead-air region occurs on each side of the cylinder wake.

To determine the effect of positioning a cylinder in the wake of another cylinder, a second cylinder was located at various positions upstream from the single cylinder shown in figure 36. In figure 37, the boundary-layer flow field of a single cylinder is compared with the resultant flow of tandem cylinders placed 3.2 diameters apart. The flow pattern of the upstream cylinder is identical to the single cylinder. The wake of the upstream cylinder confines the interference region on the instrumented cylinder to a very localized region.

The effect of extending the spacing of the tandem cylinders to 6.4 diameters is shown in figure 38. The relatively large distance between the two cylinders permits the flow to reestablish a flow field similar to that for the single cylinder. The wake of the upstream cylinder causes only a slight reduction in the extent of reverse flow on the windward face of the downstream cylinder.

In figure 39 the instrumented cylinder is 3.2 diameters downstream from a dummy cylinder and offset so that a line connecting the centers of the cylinders forms an angle of $26\frac{1}{2}^{\circ}$ with the free stream. The flow fields of the two cylinders overlap and the low-energy wake is assimilated by the second cylinder shock wave.

In figure 40 the flow field is shown for a cylinder placed 3.2 diameters downstream from a dummy cylinder, and a line connecting the centers of the cylinders forms an angle of 45° with the free stream. The flow field of the second cylinder is distorted so that the region of high turbulence is at a minimum along a line connecting the centers of the cylinders. The flow-visualization photographs of all cylinder projections show, in the region of the flow field enclosed by the shock boundary-layer interaction, a third line of flow discontinuity forming

a "herringbone" pattern in the oil. In this particular configuration, this third line is directed toward the second cylinder. Heat-transfer tests (ref. 4) indicate that this wake location causes a maximum heat-transfer coefficient on the flat plate just upstream from the second cylinder.

The effect of sweep on the flow pattern of a single circular cylinder is illustrated in figures 41 and 42. The flow field for the 45° sweptback cylinder is illustrated in figure 41. The low Reynolds number photograph (fig. 41(a)) illustrates the streamlines along the windward portion of the cylinder. The area of high shear on the flat plate influenced by the swept cylinder is confined to a very small region, extending upstream less than 0.3d.

The largest region of high shear from shock boundary-layer interaction for any single cylinder configuration results from sweeping the cylinder 45° forward as illustrated in figure 42. The reverse flow extends 3 diameters upstream, and the area of interaction is comparable to that obtained with the two-dimensional stiffener models. The third line of flow discontinuity resembling a "herringbone" line, noted in figure 40, is well defined to its origin, slightly upstream from the stagnation line of the cylinder. The dead-air region on the leeward side of the cylinder is more extensive than that of any of the other cylinder configurations. The concentration of oil on the leeward side of the cylinder indicates a large region of dead air. Heat-transfer results presented in a subsequent section of this report show that this cylinder configuration gave maximum heat-transfer coefficients on the flat plate at the stagnation line of the cylinder.

Pressures

Boundary layer.- The boundary-layer profile was measured with the rake illustrated in figure 32 at 40.47 inches and 116.47 inches downstream from the leading edge of the flat surface spanning the tunnel on the horizontal center plane. The tunnel side-wall boundary layer was measured at the position of the instrumented cylinder with the large rake shown in figure 33. The boundary-layer profile was determined from $p_{t,2}$ and p_s , with p_s assumed to be constant through the boundary layer and of the magnitude determined by the tube at $z = 3$ inches on the small rake and by the tube at $z = 3\frac{3}{8}$ inches on the large rake.

The results are listed in table II-1 and typical Mach number profiles are depicted in figure 43. The inner five tubes of the small rake distorted the boundary-layer profile in the vicinity of the wall. The local free-stream Mach number M and boundary-layer thickness δ are as follows:

M	R	Rake station, in.	M_L	δ , in.
2.65	4.87×10^6	116.47	2.64	1.47
	3.14	116.47	2.66	1.47
	1.60	116.47	2.61	1.47
	4.79	40.47	2.70	.70
	3.09	40.47	2.63	.56
3.51	4.78	116.47	3.41	1.47
	3.33	116.47	3.41	1.67
	1.89	116.47	3.38	1.67
	4.61	40.47	3.37	.70
	3.06	40.47	3.21	.70
4.44	4.34	116.47	4.13	1.67
	3.04	116.47	4.09	1.76

The measured boundary-layer thicknesses were in good agreement with δ predicted by equation (7) of reference 11. Although the boundary-layer thickness δ varies with M and R, the nominal value of δ at $x = 40.47$ is 0.7 inch and at $x = 116.47$ is 1.5. The nominal tunnel side-wall value of δ is 6 inches.

Pressure coefficients.— The distribution of pressure coefficients on the flat plate alone and in the vicinity of the stiffener and cylinder models is listed in table II-2 and is plotted in figures 44 to 48. Conversion of the flat-plate pressure coefficients to local values of M by assuming the local total pressure is the same as that in the free stream and comparison of the pressure data for both the forward and aft positions of the test plate indicate that the value of M along the plate in the aft position is approximately 0.03M higher than that in the forward position.

The flat-plate pressure coefficients for the stiffener models are presented in figure 45. The oil-flow photographs indicate that all orifices are in separated flow. Comparison of the measured pressures with the critical pressures associated with separation of a turbulent boundary layer (ref. 12) shows that measured values are approximately 20 percent below theoretical values for Mach numbers of 2.65 and 3.51 and have fair agreement at a Mach number of 4.44.

Superposition of pressures measured in the vicinity of cylinders located in three positions along the test plate center line (fig. 1) in the nominal 1.5-inch and the nominal 6-inch flat-plate boundary

layers is shown in figure 46 and illustrates the extent of the interaction of the cylindrical bow shock wave with the flat-plate boundary layer. The $2\frac{1}{2}$ -inch offset of the pressure orifices from the flat-plate center line prevents the determination of the maximum upstream effect of the cylinders. However, the pressures indicate that the cylindrical bow shock is apparently lambda footed and divided into two pressure hills upstream from the cylinder with the maximum pressure rise occurring in the vicinity of the bow shock. For an approximately constant boundary-layer thickness and Reynolds number per foot, the pressure distributions are similar throughout the test Mach number range.

Increasing the flat-plate boundary layer from 1.5 inches to 6 inches results in an attenuation of the interaction phenomena, but the overall pressure distributions are similar (i.e., maximum C_p at $M = 2.65$ is 0.38 in the 1.5-inch boundary layer and 0.28 in the 6-inch boundary layer).

Dissipation of the interaction phenomena in the lateral plane of the cylinder is defined by superposition of pressures obtained on cylinders located at three spanwise stations with a constant distance from the flat-plate leading edge. (See fig. 47.) The peak pressure coefficients are in the region of the main cylinder shock and decrease in magnitude and occur farther downstream with increasing lateral distance from the cylinder as the bow-shock intensity decreases. The lambda shock also sweeps back, but the decrease in magnitude is slight. The effect of increasing the boundary layer from 1.5 inches to 6 inches is to decrease the measured peak C_p .

Figure 48 illustrates the pressure distribution upstream from a circular cylinder at three angles of sweep: 0° , 45° forward, and 45° back. The pressure orifices extend from 7.5 inches to 16.5 inches upstream. As noted in the preceding discussion, the offset of the pressure orifices from the flat-plate center line prevents determination of the maximum upstream effect of shock interaction. However, the effect of sweep and the slight effect of boundary-layer thickness is readily discernible. At 0° sweep the separated flow extends 2.1 cylinder diameters upstream for all boundary-layer thicknesses. At 45° sweepforward the separation extends 3.4 diameters upstream for the 0.6-inch and 1.5-inch boundary layers and increases to 3.8 diameters upstream for the 6-inch boundary layer.

Heat Transfer

Flat plate.- No theory exists for the prediction of the effect of a projection of arbitrary cross section on the local heat-transfer

coefficient of the adjacent surface. This investigation experimentally determines the effect of different protuberance configurations on the adjacent surface by dividing, at a particular thermocouple, the local heat-transfer coefficient of the flat plate with a protuberance by the local heat-transfer coefficient of the flat plate without a protuberance. This ratio is referred to hereinafter as h/h_0 . The results of this investigation are presented in this form in tables III, IV, and V. The scope of this investigation necessitated testing in three separate phases. At the beginning and conclusion of each phase the basic flat plate was tested at each Mach number and Reynolds number to determine the reliability of each thermocouple and the agreement of each phase. This comparison indicated a shift in the average level of heat transfer between the first and subsequent phases. This shift was attributed to the location of the stagnation-temperature probe. In the first phase the probe was located above the support structure, and the gradient in the stagnation temperature resulted in a temperature lower than that in the region of the test surface. In subsequent phases the probe was located below the support structure on the side of the test surface. Because the stagnation temperature is used in the computation of the heat-transfer coefficient, it is necessary when comparing a flat-plate heat transfer with a model heat transfer that the stagnation temperature be measured at the same location. Consequently all protuberance heat-transfer measurements in phase I are divided by a flat-plate value of phase I and all protuberance heat-transfer measurements in subsequent phases are divided by flat-plate values in the corresponding phase. The final listing of the heat-transfer coefficients of the flat plate alone is taken from those phases in which the stagnation probe is located on the same side of the support structure as the test surface. A comparison of flat-plate heat-transfer coefficients obtained with the probe located on the side opposite the test surface with the flat-plate values, as presented in tables III and IV for the same test conditions, indicates that for a nominal 0.7-inch boundary layer the heat-transfer coefficients were 15 percent higher and for a nominal 1.5-inch boundary layer the coefficients were 20 percent higher than those of the flat plate alone. Although the value of the heat transfer in the first phase is not comparable to that in any other phase, the ratio h/h_0 is valid.

The interchangeability and relocation of the test plate in figure 1 on the support assembly spanning the tunnel on the horizontal center plane permitted the location of the projections in two boundary-layer thicknesses. (See fig. 6.) As discussed in the section entitled "Boundary layer," the boundary-layer thickness on the test surface mounted on the tunnel horizontal center plane was measured at the position of the instrumented cylinder on the plate in the forward position and at a station 116.47 inches downstream from the leading edge with the test surface in the aft position. The nominal boundary-layer thickness in the forward position was 0.7 inch and 1.5 inches in the aft

position. With the test surface mounted on the tunnel side wall the nominal side-wall boundary-layer thickness was 6 inches. These boundary-layer thicknesses are used to identify the location of the test surface for each model configuration.

The axial distance x for the thermocouples on the flat plate are always measured from the leading edge of the test flat plate. The leading edge of the test plate is 12 inches from the origin of the boundary layer (leading edge of the wing-type support structure) for the nominal value of δ of 0.7 inch and 60 inches from the boundary-layer origin for the nominal value of δ of 1.5 inches. The flat-plate heat-transfer coefficients for all of the thermocouples on the flat plate mounted in the 0.7-inch and 1.5-inch boundary layers are presented in tables III-1 and IV-1 and are compared with the Van Driest flat-plate theory (ref. 13) in figures 49 and 50. The theory is evaluated for $M_L = M_\infty$, $T_w/T_\infty = 2.0$ for $M_L = 2.65$, $T_w/T_\infty = 3.0$ for $M_L = 3.51$, and $T_w/T_\infty = 4.0$ for $M_L = 4.44$ for an assumed value of Ng_t of $0.6c_f$. In the minimum boundary layer, the differences between measured heat-transfer coefficient and theoretical values are within the accuracy of heat-transfer measurements. In the 1.5-inch boundary layer, the experimental values are less than those predicted by Van Driest theory and the variation of Stanton number with Reynolds number is less than that predicted. The increase in local Mach number associated with the tunnel nozzle expansion, as discussed in the section entitled "Accuracy," causes a reduction in the measured heat-transfer coefficient; however, adjusting the theoretical calculations for this slight Mach number effect decreases the discrepancy between theory and experiment, but the result is not of the proper magnitude.

Stiffener projections.— Surface projections cause separations of the local flow; the extent of this separation both upstream and downstream and the magnitude of the resultant heat-transfer-coefficient variation are dependent upon size, cross-sectional shape, Mach number, Reynolds number, and boundary-layer thickness. The effect of these variables on the heating distribution in the vicinity of the two-dimensional section (along the flat-plate center line) of the three-dimensional models in figure 8 is illustrated in figures 51 to 57. With the exception of the 1-inch by 2-inch stiffener these models were only tested in the 6-inch boundary layer. The 1-inch by 2-inch stiffener, used with the 2-inch by 4-inch rectangular stiffener to determine scale effect, was also tested in the 1.5-inch boundary layer.

The effect of Mach number and Reynolds number on the heating distribution on the flat plate with the 2-inch by 4-inch stiffener in a nominal 6-inch boundary layer is illustrated in figure 51. As illustrated in figure 51(a), the increase in heat-transfer coefficient at a Mach number of 3.51 and Reynolds number of 2.79×10^6 extends upstream

a distance greater than 3.25 projection heights. The region of low heat transfer in the wake of the projection extends approximately 2 projection heights downstream. It should be noted that the Reynolds number effect and Mach number effect are plotted for all thermocouples within $2\frac{1}{2}$ inches of the center line of the flat plate. Reynolds number effect

in figure 51(b) is negligible except in the immediate region upstream from the model. Here with an increase of approximately 60 percent in Reynolds number, the heat-transfer ratio h/h_0 increased approximately 25 percent. In the same area for a nominal Reynolds number per foot of 2.9×10^6 , the effect of increasing Mach number from 2.65 to 4.44 (fig. 51(c)) increases the value of h/h_0 approximately 60 percent. The heat-transfer coefficient in the wake is relatively insensitive to Mach number and Reynolds number. The correlation of the constant h/h_0 lines with the oil-flow pattern for the 2-inch by 4-inch rectangular stiffener is illustrated in figure 52. By observing these photographs it is easily seen that high values of h/h_0 occur in the regions of high shear (dark area along the windward face of the model).

The effect of fairing the windward face of the rectangular stiffener on the distribution of the heat transfer is illustrated in figures 53 to 55 and is listed in tables V-3 and V-4. The overall heat-transfer distribution on the flat plate for the 1/4 round fairing (fig. 53) is similar to that on the 2-inch by 4-inch rectangular stiffener. However, the maximum value of h/h_0 is reduced 30 percent.

By fairing the 2-inch by 4-inch rectangular stiffener with a 30° wedge (fig. 54), the upstream heating is reduced by 60 percent. The heat-transfer distribution in the wake is the same for all three models. Figure 55 illustrates the correlation between the oil-flow patterns and the lines of constant h/h_0 for the 30° wedge fairing. In this photograph, as in the other oil-flow photographs, the regions of high shear and lines of h/h_0 coincide. It should be noted that from a weight standpoint the 1/4 round fairing and the 30° wedge fairing incorporate approximately the same amount of material. Comparison of the three stiffener configurations indicates that the 30° wedge shows an appreciable reduction in heating on the flat plate.

The windward heat-transfer distribution on all stiffener models, as shown in figure 56, are of the same magnitude; consequently, the total integrated heat load would be largest for the 30° wedge fairing model and for heat considerations the 2-inch by 4-inch rectangular stiffener would be the optimum configuration.

The Reynolds number and Mach number effect on a 1-inch by 2-inch stiffener is illustrated in figure 57. Comparison of the 1-inch by

2-inch stiffener in figure 57 with the 2-inch by 4-inch stiffener in figure 51 illustrates the scale effect in the 6-inch boundary layer. By increasing the projection size by a factor of 2, the region of elevated heating increases from $1K$ to $2\frac{1}{2}K$. The extent of low heat transfer in the wake increases from $1K$ to $1\frac{1}{2}K$.

Comparison of the results of the 1-inch by 2-inch stiffener in both the 1.5- and 6-inch boundary layers with those of the 2-inch by 4-inch stiffener in the 6-inch boundary layer indicates that the ratio of size of the projection to the local boundary layer affects the heat-transfer ratio up to the point where $K/\delta = 1$. This effect is to increase the value of h/h_0 approximately 30 percent. There is no appreciable increase for $K/\delta > 1$.

Single cylinder.- As a means of simulating external antenna, or slab surfaces having hemicylindrical leading edges, cylinders of varying diameter and sweep were tested in the three boundary-layer thicknesses. Combinations of multiple cylinders were also tested to determine the heat-transfer distribution on projections at various positions in the wake of a second cylinder. A portion of these results has been presented in reference 4. The extent of the interference region, the effect of unit Reynolds number, and the effect of free-stream Mach number are presented in figure 58 for the 2.8-inch-diameter right circular cylinder in a 6-inch boundary layer. With the exception of a small area immediately downstream from the cylinder, the entire interference region has elevated heat-transfer coefficients. Excluding the cylinder wake, the area where $h/h_0 > 2$ is approximately 20 times the cylinder cross-sectional area. The effect of unit Reynolds number and M are confined to the stagnation region of the cylinder, where h/h_0 increases with decreasing R and increasing M . The effect of boundary-layer thickness was determined for $M = 3.51$ and $R = 2.86 \times 10^6$; however, the effect should be similar for all Reynolds numbers and Mach numbers of this investigation. By increasing the boundary-layer thickness from 0.7 inch to 1.5 inches, the effect on the area of interaction is imperceptible. However, increasing the boundary-layer thickness by a factor of approximately 10 reduces the interaction area 60 percent. The influence of boundary-layer thickness on h/h_0 along the center line of the plates (fig. 59) is confined to the region of $(h/h_0)_{\max}$ which increases with decreasing boundary-layer thickness. Within the range of this investigation $(h/h_0)_{\max}$ varies from 2.9 (for $M = 2.65$, $R = 4 \times 10^6$, and $\delta = 6$ in.) to 14.2 (for $M = 4.44$, $R = 2.1 \times 10^6$, and $\delta = 0.7$ in.).

The heat-transfer coefficients on the cylinder models h are divided by the theoretical values for laminar flow h_L as predicted by

the method of reference 14. A list of these theoretical values can be found in table VI. The agreement with theory outside of the region of flat plate and cylinder bow shock interaction is only fair. All the data presented in this report for the 2.8-inch-diameter right-circular-cylinder configurations tested in the 0.7-inch and 1.5-inch boundary layers were obtained with the stagnation probe mounted on the side of the wing-type support structure opposite the models, and as was noted in the discussion of the flat-plate heat-transfer coefficients these heat-transfer coefficients are low. A similar test described in reference 5 with a 0.030-inch-thick Inconel cylinder wall as opposed to the present test with a 0.050-inch-thick stainless-steel cylinder wall had good agreement with theory; this agreement indicated that conduction losses could be attributed to the difference in wall thickness. The wide spacing of the thermocouples at $\phi = 0^\circ$, 45° , and 90° was too large to define the circumferential conduction losses; consequently, the conduction losses in the tables are only in the z-direction on the stagnation line of the cylinder.

The intersection of the cylinder bow shock wave and the flat-plate boundary layer causes the high pressure behind the cylinder bow shock to feed upstream and radially outward in the flat-plate boundary layer which, in turn, causes a local boundary-layer thickening and local shocks. These shocks intersect the cylinder bow shock, and the resultant vortex impinging on the cylinder results in localized high heat transfer. These flow phenomena are illustrated in figure 3 of reference 15 and the flow mechanism is more thoroughly discussed in reference 5. The magnitude of this interaction is depicted in figure 60(a) for a 0.7-inch-thick boundary layer. The value of $(h/h_L)_{\max}$ increases with increasing M from 1.38 at $M = 2.65$ to 2.28 at $M = 3.51$. The value of $(h/h_L)_{\max}$ at $M = 4.44$ cannot be compared with the values at the lower Mach numbers because the thermocouple locations do not coincide with the location of the lambda shock intersection. The increase in shock-angle inclination with decreasing Mach number results in an outward movement of the intersecting shocks with decreasing M . The stagnation-line distribution of h/h_L for the three boundary-layer thicknesses is shown in figure 60(b).

In order to eliminate end effects on the cylinder heat-transfer distribution and to determine the effect of an end plate on the cylinder and the effect of resulting wake on the instrumented flat plate, a 9.0-inch by 14.1-inch flat plate with a 10° wedge was mounted on the right circular cylinder. (See fig. 60(c).) The plate caused a disturbance in the free-stream flow and a shock interaction similar to that encountered on the main support structure. The plate had no effect on the heat-transfer distribution in the wake of the cylinder. The heat-transfer distribution for a 1.4-inch-diameter cylinder, also plotted in this figure, is discussed subsequently.

Multiple cylinders.— The heat-transfer distribution at various positions in the wake of a second cylinder is determined by positioning a dummy cylinder at several locations upstream from the instrumented cylinder. The results given in this report supplement the data presented in reference 4 for the 1.5-inch-thick boundary layer at $M = 3.51$ and $R = 2.8 \times 10^6$ by presenting the data for $M = 2.65$ and 4.44 and three Reynolds numbers at each Mach number and also the results obtained in a boundary layer of 6 inches.

The theoretical stagnation-line heat-transfer distribution on the instrumented cylinder in the 6-inch-thick boundary layer does not show any radical difference for the various cylinder locations depicted in figures 61 to 65. It is evident from a comparison of these results with the results of reference 4 that the thick boundary layer diminishes the interaction heating; however, it is to be noted that the 45° offset cylinder location has the highest heating rates.

Tandem cylinders 3.2 diameters apart: The interference heating resulting from placement of the cylinders in tandem and spaced 3.2 diameters apart is illustrated in figure 61. The values of $(h/h_o)_{\max}$ on the flat plate occur at the stagnation line of the cylinders, and these values are in good agreement when the difference in thermocouple location (x/d of 0.57 upstream from the stagnation element on the forward cylinder and x/d of 0.21 for the instrumented cylinder) is taken into consideration. The $(h/h_o)_{\max}$ of the leeward cylinder can be compared with that of the single cylinder; this comparison indicates that the wake of the dummy cylinder causes a large reduction in $(h/h_o)_{\max}$. The effects of R and M (figs. 61(b) and 61(c)) are presented for the thermocouples located within a $2\frac{1}{2}$ -inch band of the flat-plate center line, and for clarity in the immediate vicinity of the cylinders only the center-line thermocouple data are presented. The trend of increasing h/h_o with decreasing R and increasing M is similar to the trend for the single cylinder, but the wake causes a reduction in the magnitude of this variation. This reduction is dependent upon M , R , and δ . For $M = 2.65$, $R \approx 4 \times 10^6$, and $\delta = 6.0$ inches, $(h/h_o)_{\max}$ is reduced only 11 percent. For $M = 4.44$, $R \approx 2.1 \times 10^6$, and $\delta = 1.5$ inches, $(h/h_o)_{\max}$ is reduced 66 percent.

Tandem cylinders placed 6.4 diameters apart: Increasing the tandem cylinder spacing to 6.4 diameters (fig. 62) permits the wake of the upstream cylinder to regain most of the free-stream velocity and as a result the $(h/h_o)_{\max}$ at the instrumented cylinder and its variation with R and M are of the same magnitude as those of the single cylinder.

Cylinders offset $26\frac{1}{2}^\circ$: In figure 63 is shown the h/h_o distribution resulting from placing the instrumented cylinder 3.2 diameters downstream from the dummy cylinder and offset so that a line connecting the centers of the cylinders forms an angle of $26\frac{1}{2}^\circ$ with the free stream. The region of elevated heating is very large and for $M = 2.65$ and 3.51 the $(h/h_o)_{\max}$ and its variation with R and M are approximately the same as those for the single cylinder. The $(h/h_o)_{\max}$ for $M = 4.44$ is greater than that for the single cylinder. As is discussed in the next section for the cylinder having the 45° offset, the maximum interference heating is related to the proximity of the cylinder bow shock wave.

Cylinders offset 45° : In figures 64 and 65 is shown the h/h_o distribution resulting from placing the instrumented cylinder 3.2 diameters downstream from the dummy cylinder and offset so that a line connecting the cylinder centers forms an angle of 45° with the free stream. The maximum heating in the vicinity of the instrumented (leeward) cylinder occurs in the ϕ quadrant that is aligned with the herringbone line (in the oil-flow patterns of fig. 40) that originates in the vicinity of the windward portion of the upstream cylinder. Since this pattern is similar to the type of flow limiting the interference region and this pattern converges with increasing M , it is postulated that this is the projection of the bow shock and that $(h/h_o)_{\max}$ occurs when the upstream cylinder bow shock impinges on the instrumented cylinder. This postulation is further substantiated by the variation of $(h/h_o)_{\max}$ with M . At $M = 2.65$, $(h/h_o)_{\max}$ is of the same magnitude as that for the single cylinder; however, at $M = 4.44$, $(h/h_o)_{\max}$ is 52 percent greater for the 45° offset cylinder than that for the single cylinder. The Reynolds number and Mach number effects are depicted in figures 64(b) and 64(c).

Cylinder scale effect.- In order to determine the scale effect, 1.4-inch-diameter cylinders were tested in the 0.7-inch and 1.5-inch boundary layers. Comparison of the contour plots (not shown herein) for the 1.4-inch-diameter single cylinder with those for the 2.8-inch-diameter single cylinder indicates that the interaction region is proportional to the cross-sectional area of the cylinder.

Single cylinder: The difference in the location of the thermocouple in the flat plate relative to the stagnation line of the cylinders having different diameters prevents any direct comparison of $(h/h_o)_{\max}$; however, the variation of $(h/h_o)_{\max}$ with R and M , as shown in the tables, is the same for the two cylinders. The h/h_L distribution

along the stagnation line (fig. 60) is considerably different for the smaller cylinders. The value of $(h/h_L)_{\max}$ is 1.6 for the small cylinder at $M = 3.51$ and $R = 2.87$ as compared with 2.24 for the large cylinder. Also, the location of $(h/h_L)_{\max}$ is inboard; this indicates that d/δ must be considered. The larger frontal area of the large cylinder restricts the flow in the vicinity of the lambda shock and causes a larger bump in the boundary layer with a correspondingly higher interaction point.

Tandem cylinders spaced 6.4 diameters apart: The $(h/h_o)_{\max}$ at the stagnation line of the leeward cylinder, for all test Mach numbers and Reynolds numbers, is greater than the measured value for the single cylinder; this indicates that the windward cylinder has added considerable turbulence to the flat-plate boundary layer and, as a result, the increase in h/h_L on the stagnation line of the cylinder, associated with the lambda shock interaction, is not discernible.

Cylinders offset $26\frac{1}{2}^\circ$: The $(h/h_o)_{\max}$ on the flat plate exceeds the value for the single cylinder. The increase of $(h/h_o)_{\max}$ at the windward cylinder over the single cylinder is greater than the increase noted at the large cylinders in the 45° offset position. The variation of $(h/h_o)_{\max}$ with M and R is similar to the results for the large cylinder. The h/h_L distribution on the 1.4-inch-diameter cylinder is the same for the tandem and $26\frac{1}{2}^\circ$ offset positions.

Effect of sweep.— In order to determine the effect of sweep on heating, tests have been made on a 2.8-inch-diameter cylinder swept 45° forward and back.

Cylinder swept forward 45° : Applying the analogy between high shear and high heating to the oil flow for the forward swept cylinder (fig. 42) indicates that this configuration has the largest windward region of high heating of all cylinder configurations studied in this investigation. Superimposing h/h_o at the thermocouple locations on the flat plate on the oil-flow photographs further substantiates the correlation of oil-flow shear to heat-transfer distribution. Comparison of the oil-flow patterns of a single and a 45° sweptforward cylinder (figs. 37(a) and 42) indicates that the region of shock-wave—boundary-layer interaction is larger for the sweptforward cylinder. However, the area bounded by the line of constant h/h_o of 2 (as shown in fig. 66(a)) is the same for both configurations. The variation of h/h_o with M and R shown in figure 66 is the same as that for the

preceding configurations. The magnitude of $(h/h_o)_{\max}$ varies from 5.6 in the 6-inch-thick boundary layer at $M = 2.65$ and $R = 3.26 \times 10^6$ to 25.3 at $M = 4.44$ and $R = 2.12 \times 10^6$. The correlation of heat-transfer ratios and oil-flow patterns is illustrated in figure 67.

The h/h_L distribution along the stagnation line of the 2.8-inch-diameter cylinder is shown in figure 68. The decrease of $(h/h_L)_{\max}$ with increasing boundary-layer thickness and the inward movement of the location of $(h/h_L)_{\max}$ with increasing M is similar to those for the right circular cylinder. In a 0.7-inch-thick boundary layer $(h/h_L)_{\max}$ on the swept cylinder is greater than that on the right circular cylinder except at $M = 4.44$.

Cylinder swept back 45° : The measured h/h_o and h/h_L distributions for the cylinder swept back 45° are shown in figures 69 and 70, respectively. The shock-wave—boundary-layer interaction on the flat plate is confined to a small region in the immediate vicinity of the cylinder. The thermocouple in the flat plate at the stagnation line of the other cylinders is covered by this configuration and, as a result, the thermocouple nearest to the stagnation line is at $x/d = 0.64$ upstream from the cylinder stagnation element as opposed to $x/d = 0.14$ for the cylinder swept forward 45° . Although $(h/h_o)_{\max}$ is not measured, the oil-flow patterns indicate a very low value of $(h/h_o)_{\max}$. The effect of sweep on interference heating is dependent upon the direction of sweep. For example, $(h/h_o)_{\max}$ for a right circular cylinder in a 1.5-inch-thick boundary layer at $M = 3.51$ and $R \approx 3 \times 10^6$ was 6.83; for the same test conditions with the cylinder swept back $(h/h_o)_{\max}$ was 2.07 and with the cylinder swept forward $(h/h_o)_{\max}$ was 11.14. The configuration in figure 14(a) was used to obtain $(h/h_o)_{\max}$ at 45° sweepback. This model has a 45° sweptback hemicylindrical leading edge with a diameter comparable to that of the 2.8-inch-diameter cylinder.

On the stagnation line of the cylinder $(h/h_L)_{\max}$ decreases with increasing boundary-layer thickness. In the 6-inch-thick boundary layer only the thermocouples outside the flat-plate boundary layer have values of h/h_L greater than 1. The magnitude and distribution of h/h_L in the 0.7-inch and 1.5-inch boundary layers suggest that a portion of the flat-plate boundary layer flows along the leading edge of the cylinder and that all values of h/h_L are greater than 1. The variation of h/h_L with M is not discernible on this configuration.

Specific protuberances.— The previously discussed configurations are general adaptations of standard geometric shapes. Results of combinations of these shapes produce heating rates that are different from those produced by any one of the single components and are discussed in the following sections. Typical configurations of protuberances, such as those shown in figure 14, are representative of actual fairings for electrical conduits, helium pressure lines, fuel lines, and other external piping of a launch vehicle. The effect of these specific protuberances on the heat-transfer distribution on the flat-plate surface for $M = 3.51$, $R = 2.8 \times 10^6$, and $\delta = 1.5$ inches is illustrated in figure 71.

26° fairing: The cylindrical-pipe configuration with a 26° conical fairing has a heat-transfer distribution as illustrated in figure 71(a). The upstream interference heating is negligible.

The pipe with axis alined to the free stream and extending downstream from the fairing has a spacing between cylinder wall and flat plate of $0.38z/\delta$ and is completely immersed in the boundary layer. From general observations it might be assumed that the location of this pipe would prevent elevated values of h/h_0 in the wake of the upstream fairing. The turbulent wake of the fairing causes the elevated heating pattern shown in figure 71(a) and is similar to that produced by the single cylinder of this report and of reference 4 for the same boundary-layer thickness.

45° fairing: The cylindrical-pipe configuration with a 45° fairing produces a heat-transfer distribution as shown in figure 71(b). The value of $(h/h_0)_{\max}$ is increased 100 percent over that for the 26° fairing, and its effect is felt approximately 1K upstream from the protuberance.

The pipe with axis alined to the free stream and extending downstream from the fairing has a maximum spacing between cylinder wall and flat plate of $0.29z/\delta$. A cylindrical shroud diminishes the spacing at one location to a value of z/δ of 0.15. The h/h_0 distribution in the wake is similar to that for the 26° fairing.

Lox line: The configuration illustrated in figure 14(c) has a heating distribution as shown in figure 71(c). This fuel-line configuration has many shrouds, fairings, and ring stiffeners and is normal to the flow at the flat-plate surface. The value of K/δ for the lox line has been reduced 66 percent as compared with that for the right circular cylinder of reference 4. Consequently, the interaction phenomena of the bow shock and flat-plate boundary layer are reduced and therefore the value of $(h/h_0)_{\max}$ is only 50 percent of that for the right circular cylinder of reference 4 for the same δ .

The portion of the pipe aligned with the flow had the space between the cylinder projections and flat-plate surface to vary from $z/\delta = 0.01$ to $z/\delta = 0.15$. High heating rates occurred in the vicinity where the shrouds or ring stiffeners approached the flat-plate surface, and the overall h/h_0 pattern in the wake is similar to the patterns for the 26° and 45° fairing models.

30° cableway: The stiffener model illustrated in figure 13 has a flat-plate h/h_0 distribution as shown in figure 71(d). This heating distribution is very similar to that for the 30° wedge stiffener model in figure 54. The ratio K/δ is the same and the region of high heating occurs approximately 2K upstream for both models. The downstream distribution of h/h_0 in the wake is also similar to that for the large model.

CONCLUDING REMARKS

Surface protuberances and projections cause separations of the local flow; the extent of this separation both upstream and downstream and the magnitude of the resultant interference heat-transfer coefficients and their distribution are dependent upon size, cross-sectional shape, Mach number, Reynolds number, and boundary-layer thickness. The extent of the interference region can be defined by either static-pressure distributions or by use of the oil-flow technique. In all configurations tested, contour plots of the distribution of heat-transfer ratio h/h_0 agreed with the regions defined by the oil-flow photographs.

The heat-transfer distributions in the vicinity of two-dimensional projections having varying cross sections indicate that the upstream heat transfer can be reduced by decreasing the inclination of the front face. The windward interference heating rates increase with decreasing boundary-layer thickness. The maximum heating rate occurs at a ratio of projection height to boundary-layer thickness of 1. The effects of Mach number and Reynolds number are confined to the immediate vicinity of the windward face of the projection. The value of h/h_0 increases with decreasing Reynolds number and increasing Mach number. In dead-air regions immediately behind these projections h/h_0 is considerably less than that for the undisturbed flow. Downstream from this undisturbed region h/h_0 in the wake is greater than that in the undisturbed flow, but the magnitude and distribution are insensitive to Reynolds number and Mach number in the range of this investigation.

On the two-dimensional models totally immersed in the flat-plate boundary layer, the heating rates on the windward face are the same for a front face normal to the flow or swept back 60° (30° cableway).

Interference heating rates in the vicinity of cylinders projecting through the flat-plate boundary layer exhibit the same variation with Mach number, Reynolds number, and boundary-layer thickness as noted for the two-dimensional section models. The effect of sweep on interference heating is dependent upon the direction of sweep (forward or back). For example, the maximum heat-transfer ratio $(h/h_o)_{\max}$ for a right circular cylinder in a 1.5-inch-thick boundary layer at a Mach number of 3.51 and a Reynolds number of approximately 3×10^6 was 6.83; for the same test conditions with the cylinder swept back 45° $(h/h_o)_{\max}$ was 2.07 and with the cylinder swept forward 45° $(h/h_o)_{\max}$ was 11.14.

On the cylindrical projections the lambda footed bow shock causes a localized region of high heating. The location of this high heating region is dependent upon Mach number and boundary-layer thickness. Cylindrical projections also exhibit a scale effect. The size of the bow-shock-wave—boundary-layer interaction increases with frontal area and causes a shift in the location of the interference heating on the cylinder. Locating a cylinder in the influence of a second cylinder causes a large variation in the interference heat-transfer distribution. The most critical location of the cylinder is in the vicinity of the upstream cylinder bow shock.

Three of the specific configurations studied have pipes aligned with the free stream and extending downstream from the fairing. Although the spacing between the cylindrical-pipe wall and the flat plate decreased to a value of the ratio of distance from longitudinal axis to boundary-layer thickness of 0.01, the heating distribution in the wake indicated the same increase in heat transfer as was noted in the wake of cylinder projections normal to the flat plate.

TABLE I.- LOCATION OF THERMOCOUPLES AND PRESSURE ORIFICES AND
RELATIVE POSITION OF PROJECTIONS - Concluded

(b) Location of pressure orifices in flat-plate surface

x, in.	y, in.
15.5	2.5
16.5	2.5
17.5	2.5
18.5	2.5
19.5	2.5
20.5	2.5
21.5	2.5
22.5	2.5
23.5	2.5
24.5	2.5

(c) Location of model origins relative to test plate origin

Model	x, in.	y, in.
2-inch by 4-inch rectangular stiffener	25.0	-12.0
2-inch by 4-inch stiffener with 1/4 round fairing	25.0	-12.0
2-inch by 4-inch stiffener with 30° wedge	25.0	-12.0
1-inch by 2-inch rectangular stiffener	25.5	-12.0
2.8-inch-diameter instrumented cylinder	32.0	.0
2.8-inch-diameter instrumented cylinder swept forward 45°	32.2	.0
2.8-inch-diameter instrumented cylinder swept back 45°	31.8	.0
1.4-inch-diameter instrumented cylinder	32.0	.0
30° cableway	27.0	-12.0
26° fairing	30.6	.0
45° fairing	30.7	.0
Lox line	30.6	.0

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued

1. Flat Plate Alone - Continued

(e) $M = 3.51$; $R = 2.85 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued

2. 1-inch by 2-inch rectangular stiffener - Continued

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued

5. 1.4-Inch-Diameter Instrumented Cylinder - Continued

(d) $M \approx 3.51$; $R \approx 3.93 \times 10^6$

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued

5. 1.4-Inch-Diameter Instrumented Cylinder - Continued

(g) $M = 4.44$; $R = 4.37 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued

6. 1.4-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream, Offset 26.5° - Continued

(c) $M = 2.65$; $R = 1.28 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec- $^\circ R$.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued7. 2.8-inch-diameter cylinder swept forward 45° - Continued(c) $M = 3.51$; $R = 4.02 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec- $^{\circ}R$.

TABLE III. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 0.70$ INCH - Continued8. 2.8-inch-diameter cylinder swept back 45° - Continued(c) $M = 3.51$; $R = 2.76 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

1. Flat Plate Alone - Continued

(e) $M = 3.51$; $R = 2.80 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

2. 1-inch by 2-inch rectangular stiffener - Continued

(g) $M = 4.44$; $R = 4.64 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

9. 1.4-Inch-Diameter Instrumented Cylinder - Continued

(c) $M = 2.65$; $R = 1.29 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

9. 1.4-Inch-Diameter Instrumented Cylinder - Continued

(f) $M = 3.51$; $R = 1.65 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

10. 1.4-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream - Continued

(c) $M = 2.65$; $R = 1.28 \times 10^6$

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

11. 1.4-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream, Offset 26.5° - Continued

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

11. 1.4-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream, Offset 26.5° - Continued

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued13. 2.8-inch-diameter cylinder swept back 45° - Continued(b) $M = 2.65$; $R = 2.57 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec- $^\circ R$.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued14. 30° Cableway - Continued(e) $M = 3.51$; $R = 2.84 \times 10^6$

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

L-2024

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

16. 45° Fairing
(a) $M = 2.65$; $R = 4.01 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued16. 45° Fairing - Continued(f) $M = 3.51$; $R = 1.65 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

17. Lox line - Continued

(b) $M = 2.65$; $R = 2.59 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec-°R.

TABLE IV. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 1.50$ INCHES - Continued

17. Lox line - Continued

(g) $M = 4.44$; $R = 4.61 \times 10^5$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

5. 1-inch by 2-inch rectangular stiffener - Continued

(c) $M = 3.51$; $R = 2.77 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in $\text{Btu}/\text{ft}^2\text{-sec-}^\circ\text{R}$.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

6. 2.8-Inch-Diameter Instrumented Cylinder - Continued

(d) $M = 3.51$; $R = 3.96 \times 10^6$

^a Thermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

7. 2.8-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 3.2 Diameters Upstream - Continued

(b) $M = 2.85$; $R = 2.56 \times 10^6$

^a Thermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

7. 2.8-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 3.2 Diameters Upstream - Continued

(e) $M = 3.51$; $R = 2.77 \times 10^6$

^a Thermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

8. 2.8-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream

(a) $M = 2.65$; $R = 3.89 \times 10^6$

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec-°R.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued

8. 2.8-Inch-Diameter Instrumented Cylinder and Dummy Cylinder 6.4 Diameters Upstream - Continued

^aThermocouple locations for which z and/or β stations are provided are for models; x and y stations for these models are measured from model origins.

^b h measured in Btu/ft²-sec- $^{\circ}R$.

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec- $^\circ R$.

TABLE V. - HEAT-TRANSFER MEASUREMENTS FOR VARIOUS PROTUBERANCE SHAPES; $\delta = 6.00$ INCHES - Continued11. 2.8-inch-diameter cylinder swept forward 45° - Continued(c) $M = 2.65$; $R = 1.25 \times 10^6$

^aThermocouple locations for which z and/or ϕ stations are provided are for models; x and y stations for these models are measured from model origins.

^bh measured in Btu/ft²-sec- $^\circ R$.
